RESEARCH ON ASCORBIC ACID (REPORT NO 4):
THE ACTION OF GLUTATHIONE ON ASCORBIC ACID (PART II)

* Yoshinosuke Fujimura
Graduate student in Agriculture

(Dietetic Chemistry Laboratory, Department of Agriculture,
Kyoto Imperial University)

Received [redacted]

STAT

A. FOREWORD

In Report No 1, this author demonstrated chemically ~~analytically~~ that the protective action of glutathione on ascorbic acid is proportional to the amount of glutathione used and that the presence of any active enzyme is not required to effect this protective action. At the same time, in regard to this reaction in a living organism, this writer stated that the ~~presence~~ of an active enzyme is not necessarily required for the protective action of glutathione on ascorbic acid because it is considered that the quantitative relationship between glutathione and other various biochemical substances are better accomplished in the living organism than ~~can be~~ ~~performed~~ in vitro.

This report, extending the above experiment, discusses a test made to determine whether glutathione can still protect ascorbic acid when the acid is about to undergo sudden oxidation by specific outside influences. For this purpose, strong ascorbic acid oxidase was employed as a catalyst on ascorbic acid and the protective action of glutathione was tested during the oxidation

*[Note: 藤村吉之助, which can be also read Kichinosuke FUJIMURA.]

process.

The above test was made also to determine the minimum concentration strength necessary to elicit clear-cut protective action from glutathione on a given quantity of ascorbic acid and to test the effect of this minimum concentration on reaction system concentration of hydrogen ions. The following is the report on above-described tests.

D. TEST RESULTS AND THE EVALUATIONS

I. The Effect of Glutathione When Ascorbic Acid Oxidase is used as a catalyst on Ascorbic Acid

(a) Preparation of Ascorbic Acid Oxidase:

320 cc suspension solution of ascorbic acid oxidase was made according to the methods of S. W. Johnson and S. S. Zilva.

(b) Determination of Activity Degree of Ascorbic Acid Oxidase Suspension Solution:

The activity degree of ascorbic acid oxidase suspension solution made by the above-cited methods was determined by testing with solutions of compositions given in Table 1.

TABLE 1
COMPOSITION OF TEST SOLUTIONS USED IN DETERMINING THE ACTIVITY DEGREE OF ASCORBIC ACID OXIDASE SUSPENSION SOLUTION

	(cc)
Ascorbic Acid solution (100 mg%)*	25
Ascorbic Acid Oxidase suspension solution	10
Sörensen phosphate buffer solution pH=5.28	<u>65</u>
Total quantity	100

* In preparation of ascorbic acid solution, used Sörensen phosphate buffer solution pH 5.20 as a solvent. Made at Biocoat and Dolder Basel, Switzerland.

The above-described test solution was carefully placed in a 24 degree thermostat and the ascorbic acid in the thermostat was measured at definite intervals. The method of measuring was the same as that described in Report No 1 (3). However, the test solution was tested with 5 cc of 10x dilute solution. All the ascorbic acid solutions and glutathione solutions used in all the following tests were made on the day of use. The test results are shown in Table 2.

TABLE 2
QUANTITY CHANGE OF ASCORBIC ACID RESULTING FROM
ASCORBIC ACID OXIDASE

	Residue (mg)		-	12.46
after 4 hours	Titration value (cc)	I II M	0.98 0.98 0.98	0.436 0.436 0.436
	Residue (mg)		17.24	7.70

As is clear from Table 2, when the ascorbic acid oxidase is applied to ascorbic acid, the ascorbic acid rapidly reduces with the passage of time, and in four hours it becomes only 1/2.5 of the original quantity. On the other hand, comparative test A does not show a marked change. By this fact, it can be clearly recognized that the above-described suspension solution of ascorbic acid oxidase can sufficiently accelerate the oxidation of ascorbic acid. Utilizing this fact, the following test was conducted:

(c) The Effect of Glutathione on Ascorbic Acid When Ascorbic Acid Oxidase is Applied to Ascorbic Acid

To determine whether or not glutathione can protect ascorbic acid without being affected by an enzyme, even when the suspension solution of ascorbic acid oxidase acts upon ascorbic acid to accelerate its oxidation, a given quantity of the above-mentioned ascorbic acid oxidase suspension solution was added to a given quantity of ascorbic acid solution. To this was added varying

quantities of glutathione solution. The effect was then tested.

The composition of the test solution was that listed in Table 1, and the measurement results of ascorbic acid and glutathione solution are listed in Tables 4 and 5 and in Graph I.

Table 3

COMPOSITION OF COMBINATION USED TO DETERMINE PROTECTIVE ACTION
OF GLUTATHIONE WHEN ASCORBIC ACID WAS INCUBATED WITH ASCORBIC ACID OXIDASE

(Temperature $20^{\circ} \pm 1^{\circ}$, titrated with 10% dilute
test solution)

Item	Test Solutions			A	B	C

From Table I comparative test A shows that ascorbic acid rapidly reduces with passage of time, and is almost completely oxidized after four hours. Despite such rapid disappearance of ascorbic acid in test A, when glutathione is added in other comparative tests, ascorbic acid is very well preserved; there were residues of 6.82 mg in test B and 6.08 mg in test C even after 72 hours of testing period. This fact can be more clearly understood from Graph I.

It is clear, therefore, that glutathione still protects ascorbic acid even when ascorbic acid is treated with ascorbic acid oxidase; furthermore, it is clear that in this case the presence of an active enzyme is not necessary to elicit this protective action. Moreover, the quantitative change of glutathione in this case shows the same tendency as that set forth in Table 3.

2. Tests at Varying Temperatures with Varying Concentrations of Hydrogen Ions Influencing the Protective Action of Glutathione on Ascorbic Acid

It has already been noted in Report No 3(1) that the protective action of glutathione on ascorbic acid varies with the amount of glutathione applied to a given quantity of ascorbic acid. Few tests, however, have been made along this line. Consequently, this writer, using the following method, determined the effects

wielded upon the protective action by varying the compositions of hydrogen ion concentration and the temperatures of the reaction solution.

First, each of the test solutions described in Table 6 were prepared, and the quantity of ascorbic acid in them was measured after oxidation in thermostats of various temperatures.

Table 6
DECOMPOSITION OF TEST SOLUTIONS USED FOR TESTING AT VARIED TEMPERATURES
AND VARIED CONCENTRATIONS OF HYDROGEN IONS AFFECTING THE PROTECTIVE
ACTION OF GLUTATHIONE ON ASCORBIC ACID

Item	Test Solutions

Total quantity (cc)	50	50	50	50	50	50

* Type of buffer solution and pH values were changed at each test, and each buffer solution was used as a solvent for the ascorbic acid and glutathione solutions.

(a) Effects of Temperature Change With Hydrogen Ions
Concentration of pH=2.00 (N/1000 HCl)

Test solutions of Table 6 were placed in thermostats with

temperatures of $12^\circ \pm 1^\circ$, $24^\circ \pm 1^\circ$ and $36^\circ \pm 1^\circ$ and the ascorbic acid remaining in each solution was measured one hour later. Results are shown in Tables 7 to 9 (4cc of 10% dilute was used to measure the test solution).

(b) Results of Changing Temperatures at Hydrogen Tens
of Concentration pH = 5.28 (Sørensen Phosphate Buffer Solution)

Test solutions tabulated in Table 6 were placed in thermostate with temperatures of $12^\circ \pm 1^\circ$, $24^\circ \pm 1^\circ$, and $36^\circ \pm 1^\circ$ and after a given period the quantity of ascorbic acid was measured by the same method used in (a). The results are listed in Tables 10 to 12. One of 10x dilute of the test solution were used for measurement.

(c) Results of Varying Temperatures With Hydrogen Ion Concentration of pH = 7.00 (Sørensen Phosphate Buffer Solution)

The test solutions described in Table 6 underwent reactions in thermostats of $12^\circ \pm 1^\circ$, $24^\circ \pm 1^\circ$ and $36^\circ \pm 1^\circ$ temperatures, and the quantity of ascorbic acid was determined after a given period of time by utilizing the same method of tests (a) and (b). The

results are shown in Tables 13 to 15. The analysis was made with
1cc of 10x dilute of the test solution.

In assembling the results of the tests listed in Tables 7 to 9, 10 to 12, and 13 to 15, the minimum concentration effecting protective action of glutathione on ascorbic acid is approximately constant for each test solution. In other words, in comparison with test A, the result of the test B is always the same under each circumstances and does not show any protective action, but protective

7

action begins to appear partly in test C, and the action becomes pronounced in test D. The protective action becomes very pronounced with tests beyond D. The protective action of glutathione on ascorbic acid has no relation to the kind of buffer solution or the temperature of the reaction system and hydrogen ion concentration. Only two kinds of buffer solution were used; phosphate buffer solution and 1/1000 HCl, but this statement is true at least within the limits of the experiment. The protective action appears when the glutathione and ascorbic acid are mixed in the proportions used in test solutions C and D. Consequently, it may be concluded that the minimum concentration necessary to elicit the protective action of glutathione on ascorbic acid [redacted] within the conditions of the above test, that is, with temperature from 12° to 36° and pH from 2.00 to 7.00, is that of 0.004 to 0.006 mg of glutathione added to 5 mg ascorbic acid.

In an animal organism, this kind of protective action will not only be exerted by glutathione, but also by other various unknown factors. Consequently, it is still too early to apply this result immediately *in vivo*, but in general, it would probably be safe to accept the above minimum concentration for application *in vivo*.

Borsig and his co-researches (4) tested the reducing function of glutathione on dehydro-ascorbic acid and reported that the reduction potential of ascorbic acid is not related to the oxidizing agent or to the composition of the buffer solution of its reaction system. Furthermore, in regard to the hydrogen ion concentration, the reduction potential increases as the pH increases.

They also stated that this reduction potential is stronger than the formation ^{of} ~~ability~~ of irreversible materials in dehydro-ascorbic acid.

However, according to the above tests, the protective action of glutathione on ascorbic acid has no relation to the pH value within the range pH 2.00 to 7.00. If ascorbic acid once becomes dehydro-ascorbic acid by aerobic condition in the test solution and is then again reduced to ascorbic acid by glutathione, then the protective action of glutathione on ascorbic acid with pH value of 7.00 (since the composition of the buffer solution which was used as the test solution has no bearing according to the theory of Biesoel) should be more pronounced than with pH values of 2.00 or 5.20. This theory does not conform with results of the tests made by this writer, and in the mechanism of protective action of glutathione on ascorbic acid, if glutathione reduces it to the moment of oxide formation in each oxidation process of ascorbic acid, the reduction effect of glutathione may differ in its method of reduction between the case of oxidizing products and the case of dehydro-ascorbic acid.

Many tests have been made on the degree of stability of ascorbic acid and it is a generally well known fact that ascorbic acid is comparatively stable at a low temperature or in an acid area, but unstable in a high temperature or in an alkali area. However, these tests were mostly made in living tissue. Crystalline ascorbic acid solutions were used in the tests of Table 7 to 9, 10 to 12, and 13 to 15 and proved the above fact by compositions of various temperatures and pH. In other words, when hydrogen ion concentration is held constant, ascorbic acid is far more stable

under low temperature than high temperature, and under constant temperature, it is far more stable when the hydrogen ion concentration is low than when the hydrogen ion concentration is large. In the relationship of temperature and hydrogen ion concentration, pH 2.00 and $36^{\circ} \pm 1^{\circ}$ (Table 9) compared with pH 7.00 and temperature $12^{\circ} \pm 1^{\circ}$ (Table 13), 90 minutes after the test started, the residual weight of ascorbic acid in the test solutions from A to F in the former (Table 9) was 1.43 to 1.59 mg, but on the other hand, the latter (Table 13) shows only 0.11 mg of residue in each test solution. From this result, it is understood that pH is a more important factor than temperature in regard to the degree of stability of ascorbic acid.

C. SUMMARY

In regard to the protective action of crystalline glutathione on ascorbic acid solution:

1. When ascorbic acid is subjected to oxidation decomposition by serum ascorbic acid oxidase in the presence of glutathione, the ascorbic acid is well protected by the glutathione and the extent of protective action is in direct proportion to the quantity of glutathione present. Furthermore, the presence of an enzyme is not required to elicit this protective action.
2. The minimum concentration necessary for glutathione to exert protective action on ascorbic acid was determined by varying the reaction temperatures and the hydrogen ion concentrations. In other words, at temperatures between 12° to 36° and pH values between

2.00 to 7.00, 0.004 to 0.006 mg of glutathione is the minimum concentration necessary to exert protective action on 5 mg of ascorbic acid, and this minimum concentration has no relation to the test temperature or to the pH value.

3. Crystalline ascorbic acid, as within living tissues, is comparatively stable in an acid area or at low temperatures and unstable in an alkali area or at high temperatures. Furthermore, it was made clear that in regard to the stability of ascorbic acid the hydrogen ion concentration is a more important factor than temperature so far as the validity of the above test is concerned.

In conclusion, I want to express my deep appreciation to my teacher, Doctor Kinsuke Kondo, Doctor of Agriculture Science at Kyoto Imperial University, for his guidance and encouragement and also for his efforts in reviewing this report.
